Comment on "Free-Radical Formation by the Peroxidase-like Catalytic Activity of MFeO (M = Fe, Ni and Mn) Nanoparticules"

Bernard Meunier, and Anne Robert

J. Phys. Chem. C, **Just Accepted Manuscript** • Publication Date (Web): 22 Oct 2019Downloaded from pubs.acs.org on October 22, 2019**Just Accepted**

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides "Just Accepted" as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. "Just Accepted" manuscripts appear in full in PDF format accompanied by an HTML abstract. "Just Accepted" manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). "Just Accepted" is an optional service offered to authors. Therefore, the "Just Accepted" Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the "Just Accepted" Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these "Just Accepted" manuscripts.

Comment on "Free-radical formation by the peroxidase-like catalytic activity of MFe_2O_4 (M = Fe, Ni and Mn) nanoparticles"

The peroxidase-like activity of magnetite and its connection with a neurodegenerative disease such as Alzheimer's disease has been recently questioned by our group,¹ despite claims by Gao *et al.*² Since reproducibility is the essential factor in experimental sciences, the article of Moreno Maldonado *et al.* on the peroxidase-like activity of magnetite attracted our attention.³ As a matter of fact this new report is providing additional evidences on the absence of peroxidase activity of magnetite derivatives. The following comments are not a question of semantics, but are driven by the necessity to correctly

describe the different possible origins of the oxidative stress involved in many neurodegenerative pathologies.

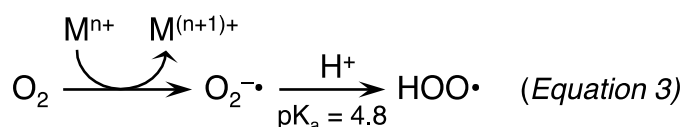

First question: are the authors really observing a "peroxidase-like catalytic activity" as claimed in the title? Peroxidases are enzymes able to perform the 2-electron oxidation of a substrate AH_2 using hydrogen peroxide as oxidant (see equation 1).

Mechanistic details concerning peroxidases and biomimetic models are available in text-books.^{4,5} The authors did not report the catalytic oxidation of a peroxidase substrate, but they detected by spin-trap methods the presence of two radicals, $HO\bullet$ or $HOO\bullet$, derived from the reaction of hydrogen peroxide or molecular oxygen, respectively, with low-valent metal ions. The hydroxyl radical $HO\bullet$ is the one-electron reduction product of hydrogen peroxide, generated by a low-valent metal ion in a Fenton-type reaction (see equation 2).

The hydroperoxyl radical $\text{HOO}\cdot$ is the protonated form of the superoxide anion $\text{O}_2^{\cdot-}$, which is the result of the one-electron reduction of molecular oxygen by a low-valent metal ion (equation 3). The protonation of superoxide anion with a pK_a value of 4.9 generates the neutral radical $\text{HOO}\cdot$ (named hydroperoxyl or perhydroxyl).⁶

These two oxygen-centered radicals are clearly not the products of a peroxidase-type reaction.

Second question: are both oxygen-centered radicals generated by a catalytic reaction?

Peroxidases are highly efficient catalysts. For instance, a 2×10^{-11} M concentration of the paradigm horseradish peroxidase (HRP) achieves oxidation of 4×10^{-5} M of tetramethylbenzidine within 5 min, in acetate buffer pH 3.5, thus giving rise to a turnover number of 2 millions of catalytic cycles within this short period of time, which corresponds to a turnover rate of 7000 cycles per second.¹ In the article by Moreno Maldonado *et al.*, the total production of $\text{HO}\cdot + \text{HOO}\cdot$ with magnetite was slightly below 2000 nM (lanes "Fe-MNP", Figure 4 of the ref. 3) for an initial concentration of Fe(II) of 1600 μM (120 μg of $\text{Fe}^{\text{II}}_{0.81}\text{Fe}^{\text{III}}_{2.19}\text{O}_4$ in 260 μL of solution, Experimental

Methods). So the yield of these two oxyl radicals was only 0.13% with respect to Fe(II), a sub-stoichiometric number, far from a catalytic activity. The reported initial concentration of H_2O_2 was 0.49 M (Experimental Methods). The production of 2 μM of $\text{HO}\bullet + \text{HOO}\bullet$ therefore corresponds to the conversion of 0.0004%, a very small fraction of the starting amount of H_2O_2 . So, the very low and non-catalytic yield of $\text{HO}\bullet + \text{HOO}\bullet$ with respect to Fe(II)] is probably the result of a Fenton-type chemistry induced by adventitious redox-active iron impurities contained in the isolated nanoparticles or generated by traces of reductants.

In conclusion, the experimental results reported by Moreno Maldonado *et al.*, provide an additional proof that magnetite nanoparticles has no peroxidase activity. In addition, the authors mentioned that "no radical formation was evidenced for any sample at $\text{pH} = 7.4$ ", a value corresponding to physiological pH. So, the biomedical claims are not consistent with the reported results. Consequently, the title of the article and all comments concerning a "peroxidase-like catalytic activity" (and putative biomedical claims) of magnetite and other ferrite nanoparticles, did not resist to a careful examination of experimental results. All the reported results can be summarized by the following sentence: "*No peroxidase activity is observed with MFe_2O_4 ($\text{M} = \text{Fe}$, Ni and Mn) nanoparticles and only traces of hydroxyl and hydroperoxyl radicals are observed at $\text{pH} = 4.8$. At physiological pH, these radicals are not detected*".
